Mathematics Section

We consider the **overdamped Langevin** equation:

$$dX(t) = f(X(t))dt + \sqrt{2}dW(t), \quad W(t), X(t) \in \mathbb{R}^d,$$

where $f = -\nabla V$, noise is additive, and $W(t)$ is a std. Wiener process.

We use **grafted forests**:

$$F_g := \left\{ \begin{array}{c} \times \\ \bullet \\ \times \times \times \\ \times \end{array} \right\}, \quad \begin{array}{c} \times \\ \bullet \\ \bullet \times \\ \bullet \end{array}, \quad \times \times, \quad \begin{array}{c} \times \times \times \\ \bullet \times \\ \bullet \end{array}, \dots \right\},$$

and **exotic forests**, which are grafted forests with paired grafted vertices:

$$EF := \left\{ \begin{array}{c} \textcircled{1} \\ \bullet \\ \textcircled{2} \textcircled{1} \textcircled{2} \end{array} \right\}, \quad \begin{array}{c} \textcircled{1} \\ \bullet \\ \bullet \textcircled{1} \\ \bullet \end{array}, \quad \textcircled{1} \textcircled{1}, \quad \begin{array}{c} \textcircled{2} \textcircled{2} \textcircled{1} \\ \bullet \textcircled{1} \\ \bullet \end{array}, \dots \right\},$$

to represent differential operators.

We consider the **overdamped Langevin** equation:

$$dX(t) = f(X(t))dt + \sqrt{2}dW(t), \quad W(t), X(t) \in \mathbb{R}^d,$$

where $f = -\nabla V$, noise is additive, and $W(t)$ is a std. Wiener process.

We use **grafted forests**:

$$F_g := \left\{ \begin{array}{c} \times \\ \bullet \\ \times \times \times \\ \times \end{array}, \begin{array}{c} \times \\ \bullet \\ \bullet \\ \bullet \end{array}, \times \times, \begin{array}{c} \times \times \times \\ \bullet \\ \times \end{array}, \dots \right\},$$

and **exotic forests**, which are grafted forests with paired grafted vertices:

$$EF := \left\{ \begin{array}{c} \textcircled{1} \\ \bullet \\ \textcircled{2} \textcircled{1} \textcircled{2} \end{array}, \begin{array}{c} \textcircled{1} \\ \bullet \\ \bullet \\ \bullet \end{array}, \textcircled{1} \textcircled{1}, \begin{array}{c} \textcircled{2} \textcircled{2} \textcircled{1} \\ \bullet \\ \textcircled{1} \end{array}, \dots \right\},$$

to represent differential operators, for example:

$$\mathcal{F}_{hf}(\begin{array}{c} \times \times \\ \bullet \end{array}) = 2h^2 \sum \xi^i \xi^j f_{ij}^k \partial_k, \quad \mathcal{F}_{hf}(\begin{array}{c} \textcircled{1} \textcircled{1} \\ \bullet \end{array}) = 2h^2 \sum f_{ii}^k \partial_k.$$

We note that $\mathcal{F}_f(\begin{array}{c} \times \times \\ \bullet \end{array})$ is a random variable, since $\xi \sim \mathcal{N}(0, I)$.

Related: Laurent and Vilmart [2019].

Preliminaries

$$\text{Deterministic case: } \frac{dy}{dt} = f(y),$$

with $y(0) \in y_0$, $y(t) \in \mathbb{R}^d$, $f : \mathbb{R}^d \rightarrow \mathbb{R}^d$ is a smooth vector field.

We can use Runge-Kutta methods:

$$Y_i = y_0 + h \sum_{j=1}^s a_{ij} f(Y_j),$$

$$y_1 = y_0 + h \sum_{i=1}^s b_i f(Y_i),$$

with

$$\begin{array}{c|ccc} c_1 & a_{11} & \cdots & a_{1s} \\ \vdots & \vdots & \ddots & \vdots \\ c_s & a_{s1} & \cdots & a_{ss} \\ \hline & b_1 & \cdots & b_s \end{array}.$$

We can Taylor expand $f(Y_i)$ around y_0 to obtain

$$y_1 = y_0 + h \sum_{i=1}^s b_i f(y_0) + h^2 \sum_{i=1}^s b_i c_i f'(y_0) f(y_0) + \cdots.$$

Consider rooted non-planar trees $T := \{\bullet, \begin{array}{c} \bullet \\ | \\ \bullet \end{array}, \begin{array}{c} \bullet & \bullet \\ \diagdown & / \\ \bullet \end{array}, \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array}, \dots\}$.

Let $a : T \rightarrow \mathbb{R}$, then a **B-series** is a formal sum $B(a) : \mathbb{R}^d \rightarrow \mathbb{R}^d$:

$$B(a) := \text{Id} + a(\bullet)hf + a(\begin{array}{c} \bullet \\ | \\ \bullet \end{array})h^2f'f + \\ \frac{a(\begin{array}{c} \bullet & \bullet \\ \diagdown & / \\ \bullet \end{array})}{2}h^3f''(f, f) + a(\begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array})h^3f'f'f + \dots$$

where all $f, f'f, f''(f, f), \dots : \mathbb{R}^d \rightarrow \mathbb{R}^d$.

Consider rooted non-planar trees $T := \{\bullet, \begin{array}{c} \bullet \\ | \\ \bullet \end{array}, \begin{array}{c} \bullet \\ / \ \backslash \\ \bullet \ \bullet \end{array}, \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array}, \dots\}$.

Let $a : T \rightarrow \mathbb{R}$, then a **B-series** is a formal sum $B(a) : \mathbb{R}^d \rightarrow \mathbb{R}^d$:

$$B(a) := \text{Id} + a(\bullet)hf + a(\begin{array}{c} \bullet \\ | \\ \bullet \end{array})h^2f'f + \frac{a(\begin{array}{c} \bullet \\ / \ \backslash \\ \bullet \ \bullet \end{array})}{2}h^3f''(f, f) + a(\begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array})h^3f'f'f + \dots$$

where all $f, f'f, f''(f, f), \dots : \mathbb{R}^d \rightarrow \mathbb{R}^d$.

Exact solution and Runge-Kutta methods are B-series.

$$\begin{aligned} a(\bullet) &= \sum b_i = 1, & a(\begin{array}{c} \bullet \\ | \\ \bullet \end{array}) &= \sum b_i c_i = \frac{1}{2}, \\ a(\begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array}) &= \sum b_i a_{ij} c_j = \frac{1}{6}, & a(\begin{array}{c} \bullet \\ / \ \backslash \\ \bullet \ \bullet \end{array}) &= \sum b_i c_i^2 = \frac{1}{3}, \\ a(\tau) &= \dots = \frac{1}{\tau!}. \end{aligned}$$

Related: Butcher [1963], Hairer and Wanner [1974], Hairer et al. [1993], Connes and Kreimer [1998], Butcher [2021].

S-series and the symmetry coefficient

B-series are based on trees, while S-series are based on forests:

$$F := \{\emptyset, \bullet, \begin{array}{c} \bullet \\ | \\ \bullet \end{array}, \begin{array}{c} \bullet \\ | \\ \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array}, \begin{array}{c} \bullet \\ | \\ \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \\ | \\ \bullet \end{array}, \dots\}.$$

The **symmetry coefficient** of trees and forests:

$$\sigma(\begin{array}{c} \bullet \\ | \\ \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array}) = 2, \quad \sigma(\begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array}) = 2, \quad \sigma(\begin{array}{c} \bullet \\ | \\ \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \\ | \\ \bullet \end{array}) = 3!.$$

S-series and the symmetry coefficient

B-series are based on trees, while S-series are based on forests:

$$F := \{ \emptyset, \bullet, \begin{array}{c} \bullet \\ | \\ \bullet \end{array}, \begin{array}{c} \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array}, \begin{array}{c} \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array}, \dots \}.$$

The **symmetry coefficient** of trees and forests:

$$\sigma(\begin{array}{c} \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array}) = 2, \quad \sigma(\begin{array}{c} \bullet \\ | \\ \bullet \end{array} \begin{array}{c} \bullet \\ | \\ \bullet \end{array}) = 2, \quad \sigma(\begin{array}{c} \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array}) = 3!.$$

S-series were introduced to study first integrals. Chartier and Murua [2006]

Given a map $\phi : \mathbb{R}^d \rightarrow \mathbb{R}$, **S-series** are defined as

$$\phi \circ B(a) = S(a)[\phi] = \sum_{\pi \in F} \frac{a(\pi)}{\sigma(\pi)} \mathcal{F}_{hf}(\pi)[\phi].$$

We consider B-series in the stochastic context. We study $\mathbb{E}[\phi(B(a))]$, and, thus, we use and extend the concept of S-series for our needs.

Order conditions for invariant measure sampling

We consider an **ergodic integrator** $\{X_0, X_1, X_2, \dots\}$ for an ergodic problem:

$$\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T \phi(X(t)) dt = \int_{\mathbb{R}^d} \phi(x) d\mu(x), \quad \text{a.s.}$$

For overdamped Langevin, we have $d\mu(x) = Ze^{-V(x)} dx$.

Order conditions for invariant measure sampling

We consider an **ergodic integrator** $\{X_0, X_1, X_2, \dots\}$ for an ergodic problem:

$$\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T \phi(X(t)) dt = \int_{\mathbb{R}^d} \phi(x) d\mu(x), \quad \text{a.s.}$$

For overdamped Langevin, we have $d\mu(x) = Ze^{-V(x)} dx$.

Definition (Weak order q and order p for inv. measure)

Given an ergodic integrator $X_n \mapsto X_{n+1}$, we have

$$\text{weak order: } |\mathbb{E}[\phi(X_N)] - \mathbb{E}[\phi(X(T))]| \leq Ch^q,$$

$$\text{inv. measure: } \left| \lim_{N \rightarrow \infty} \frac{1}{N+1} \sum_{k=0}^N \phi(X_k) - \int_{\mathbb{R}^d} \phi(x) d\mu(x) \right| \leq Ch^p,$$

where C is independent of h assumed small enough. Generally, $p \geq q$.

Order 3 conditions: **15** for weak order **vs** **9** for inv. measure.

Part 1: Exotic S-series

Overdamped Langevin: $dX(t) = -\nabla V(X(t))dt + \sqrt{2}dW(t)$,

Grafted forests: $F_g := \left\{ \begin{array}{c} \times \\ \bullet \\ | \\ \times \end{array}, \begin{array}{c} \times \times \\ \times \times \\ \bullet \bullet \\ | \quad | \\ \times \end{array}, \begin{array}{c} \times \\ \bullet \\ | \quad | \\ \bullet \bullet \\ | \quad | \\ \times \end{array}, \dots \right\},$

Exotic forests: $EF := \left\{ \begin{array}{c} \textcircled{1} \\ \bullet \\ | \quad | \\ \textcircled{2} \textcircled{1} \textcircled{2} \end{array}, \begin{array}{c} \textcircled{1} \\ \bullet \\ | \quad | \\ \bullet \bullet \\ | \quad | \\ \textcircled{1} \end{array}, \begin{array}{c} \textcircled{2} \textcircled{2} \textcircled{1} \\ \bullet \bullet \\ | \quad | \\ \textcircled{1} \end{array}, \dots \right\}.$

S-series and exotic S-series

Define S-series over grafted forests and exotic S-series over exotic forests:

$$S(a) := \sum_{\pi \in F_g} \frac{a(\pi)}{\sigma(\pi)} \mathcal{F}_{hf}(\pi), \quad ES(a) = \sum_{\pi \in EF} \frac{a(\pi)}{\sigma(\pi)} \mathcal{F}_{hf}(\pi),$$

with $\sigma(\pi)$ being a symmetry coefficient.

We prove that $ES(a) = \mathbb{E}[S(a)]$ and describe the composition law.

S-series and exotic S-series

Define S-series over grafted forests and exotic S-series over exotic forests:

$$S(a) := \sum_{\pi \in F_g} \frac{a(\pi)}{\sigma(\pi)} \mathcal{F}_{hf}(\pi), \quad ES(a) = \sum_{\pi \in EF} \frac{a(\pi)}{\sigma(\pi)} \mathcal{F}_{hf}(\pi),$$

with $\sigma(\pi)$ being a symmetry coefficient.

We prove that $ES(a) = \mathbb{E}[S(a)]$ and describe the composition law.

Theorem (Composition law)

Let $a, b : EF \rightarrow \mathbb{R}$ and let $\Delta_{CK} : \mathcal{EF} \rightarrow \mathcal{EF} \otimes \mathcal{EF}$ denote the *Connes-Kreimer coproduct*, then

$$ES(a)[ES(b)] = ES(a * b),$$

where $(a * b)(\pi) = (m_{\mathbb{R}} \circ (a \otimes b) \circ \Delta_{CK})(\pi)$ for all exotic forests $\pi \in EF$.

$$\begin{aligned} (a * b)(\text{diagram}) &= a(\emptyset)b(\text{diagram}) + a(\bullet)b(\text{diagram}) + a(\bullet \textcircled{1})b(\text{diagram}) + a(\bullet \textcircled{1} \textcircled{1})b(\text{diagram}) + a(\bullet \textcircled{1} \textcircled{1})b(\bullet) \\ &+ a(\textcircled{1} \textcircled{1})b(\text{diagram}) + a(\textcircled{1} \textcircled{1})b(\text{diagram}) + a(\text{diagram})b(\emptyset). \end{aligned}$$

Idea of the proof of $ES(a * b) = ES(a)[ES(b)]$

The exotic S-series can be written as

$$ES(a) = (\mathcal{F}_{hf} \circ A_\sigma^{-1} \circ \delta^{-1})(a),$$

where $\delta^{-1}(a) = \sum_{\pi \in EF} a(\pi)\pi$ and $A_\sigma^{-1}(\pi) = \frac{\pi}{\sigma(\pi)}$.

We define Grossman-Larson product \diamond on exotic forests as

$$\mathcal{F}_{hf}(\pi_1 \diamond \pi_2) = \mathcal{F}_{hf}(\pi_1)[\mathcal{F}_{hf}(\pi_2)]. \quad (1)$$

We analyse how $*$ changes as it passes through ES :

$$* \xrightarrow{\delta^{-1}} \circledast \xrightarrow{A_\sigma^{-1}} \diamond \xrightarrow{\mathcal{F}_{hf}} []$$

Difficulty: exotic trees can have multiple roots, e.g. , , ...

Part 2: Order conditions for invariant measure sampling

$$\Omega(\bullet) = \sum b_i - 1 = 0,$$

$$\Omega(\bullet \bullet) = \frac{1}{2} \sum b_i b_j + \frac{1}{2} - \sum b_i = 0,$$

$$\Omega(\bullet \overset{\circ}{\bullet}) = \sum b_i c_i - \frac{1}{2} + \sum b_i - 2 \sum b_i d_i = 0,$$

$$\Omega(\overset{\circ}{\bullet} \overset{\circ}{\bullet}) = \frac{1}{2} \sum b_i d_i^2 - \frac{1}{4} + \frac{1}{2} \sum b_i - \sum b_i d_i = 0.$$

Order conditions for invariant measure sampling

We present a theoretical algorithm that generates order conditions for invariant measure for arbitrary high order systematically.

$$\Omega(\pi) = 0 \quad \text{for exotic forests } \pi \in \widetilde{EF} \quad \text{with } |\pi| \leq p.$$

Order conditions for invariant measure sampling

We present a theoretical algorithm that generates order conditions for invariant measure for arbitrary high order systematically.

$$\Omega(\pi) = 0 \quad \text{for exotic forests } \pi \in \widetilde{EF} \quad \text{with } |\pi| \leq p.$$

Let \sqcup_σ denote a renormalized concatenation product of exotic forests.

Theorem (Multiplicative property of Ω for stochastic RK)

For stochastic Runge-Kutta methods, the order condition map Ω satisfies:

$$\Omega(\pi_1 \sqcup_\sigma \pi_2) = \Omega(\pi_1)\Omega(\pi_2).$$

We see that $\Omega(\text{diagram}) = \frac{1}{2}\Omega(\text{diagram})\Omega(\text{diagram})$ with $\text{diagram} \sqcup_\sigma \text{diagram} = 2 \text{diagram}$ and

$$\begin{aligned} \Omega(\text{diagram}) &= \frac{1}{2}\sum b_i d_i^2 - \sum b_i d_i + \frac{1}{2}\sum b_i - \frac{1}{4}, \\ \Omega(\text{diagram}) &= \frac{1}{8}\sum b_i b_j d_i^2 d_j^2 + \frac{1}{4}\sum b_i b_j d_i^2 - \frac{1}{2}\sum b_i b_j d_i d_j^2 + \frac{1}{2}\sum b_i b_j d_i d_j - \frac{1}{2}\sum b_i b_j d_i + \frac{1}{8}\sum b_i b_j \\ &\quad - \frac{1}{8}\sum b_i d_i^2 + \frac{1}{4}\sum b_i d_i - \frac{1}{8}\sum b_i + \frac{1}{32}. \end{aligned}$$

Labeled Transformation Chains (LTC)

We define LTC to trace the action of the algorithm on the exotic forests.

For example, the action of the algorithm on  is

$$\begin{array}{c} \textcircled{1} \quad \textcircled{1} \\ | \quad | \\ \bullet \quad \bullet \end{array} \mapsto \begin{array}{c} \textcircled{1} \\ | \\ \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array} \mapsto - \begin{array}{c} \textcircled{1} \\ | \\ \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array} - \begin{array}{c} \textcircled{1} \quad \textcircled{1} \\ | \quad | \\ \bullet \quad \bullet \end{array} - \begin{array}{c} \textcircled{1} \quad \textcircled{1} \\ | \quad | \\ \bullet \quad \bullet \end{array} - 2 \begin{array}{c} \bullet \\ | \\ \bullet \\ / \quad \backslash \\ \bullet \quad \bullet \end{array},$$

Labeled Transformation Chains (LTC)

We define LTC to trace the action of the algorithm on the exotic forests.

For example, the action of the algorithm on  is

and the list of labeled transformation chains (LTC) from  is

Each exotic tree has a single root.

Idea of the proof

The main ingredients used to prove the multiplicative property are:

- 1 we can split and combine LTC,
- 2 the algorithm generating order conditions defines a linear map,
- 3 the stochastic Runge-Kutta methods form exotic S-series $ES(a)$ with

$$a(\pi_1 \sqcup \pi_2) = a(\pi_1)a(\pi_2).$$

We use them to prove the multiplicative property:

$$\Omega(\pi_1 \sqcup_{\sigma} \pi_2) = \Omega(\pi_1)\Omega(\pi_2).$$

The following order conditions are satisfied automatically:

$$\Omega(\bullet \bullet) = 0, \quad \Omega(\overset{\bullet}{\bullet} \bullet) = 0, \quad \Omega(\overset{\textcircled{1}}{\bullet} \overset{\textcircled{1}}{\bullet}) = 0, \quad \Omega(\bullet \bullet \bullet) = 0.$$

The number of order 3 conditions for inv. measure drops from 13 to 9. This property of order 3 conditions was noticed in Laurent and Vilmart [2019] through manual computation.

Conclusion

Summary:

- 1 we defined **exotic S-series** with new symmetry coefficient, proved their relationship to S-series, and proved the **composition law**;
- 2 we introduced a **theoretical algorithm** to generate order conditions for invariant measure sampling and proved the **multiplicative property** of the generated order conditions.

Ongoing work:

- 1 description of the **substitution law** for exotic S-series;
- 2 development of a **symbolic package** for manipulation of forest-like structures. In collaboration with Jean-Luc Falcone from the Comp. Science Dep. of Univ. Geneva.

Thank you for your attention!
